Edwards coordinates
for elliptic curves

D. J. Bernstein
University of Illinois at Chicago

Joint work with:
Tanja Lange
Technische Universiteit Eindhoven
Mail sender at columbia.edu

DNS packet:
“The mail server for uottawa.ca has IP address 137.122.6.57.”

Administrator at uottawa.ca

Now columbia.edu sends mail to 137.122.6.57.
Is this system secure?

Many security holes in DNS software:
BIND libresolv buffer overflow,
Microsoft cache promiscuity,
BIND 8 TSIG buffer overflow,
BIND 9 dig promiscuity, etc.

Fix: Use better DNS software.
http://cr.yp.to/djbdns.html

But what about protocol holes?
Stealing mail by attacking DNS

Mail sender at columbia.edu

DNS packet:
“The mail server for uottawa.ca has IP address 131.193.36.27.”

Attacker anywhere on network

Now columbia.edu sends mail to 131.193.36.27. Real uottawa.ca never sees it. No warning to columbia.edu.
Are attacks really so easy?

Can attacker guess where mail is being sent?

Can attacker guess time when mail is being sent?

Can attacker guess UDP port for DNS packet?

Can attacker guess the random 16-bit ID that the mail sender puts into its DNS request?

For sniffing attackers, yes; but attackers anywhere on network?
Three weeks ago: Emergency security update for BIND to change ID generation.

Previous ID generator was cryptanalyzed by Amit Klein: “This is a weak version (since the output is 16 bits, as opposed to the traditional 1 bit) of the ... mutually clock controlled (LFSR) generator ...”

Attacker legitimately receives 13 successive IDs from sender, reconstructs stream-cipher state, predicts sender’s subsequent IDs.
Add signatures to DNS?

Long IDs and strong generators don’t stop sniffing attackers.

Obvious solution:
Public-key signatures in packets.

But many deployment obstacles: many DNS implementations; many different databases; tiny packets, 512 bytes; heavily loaded senders; heavily loaded receivers.

Current Internet situation: 0% of DNS packets are signed.
Can change DNS-security protocol to minimize effects on implementations, databases.

But still need extremely small, extremely fast signatures with extremely fast verification.

For fastest verification: state-of-the-art Rabin-Williams. But that could be trouble for signature time, space.

Let’s instead choose an elliptic-curve signature system.
Start by choosing high-speed, high-security elliptic curve: “Curve25519” (Bernstein, PKC 2006).

This is the elliptic curve \( y^2 = x^3 + 486662x^2 + x \) modulo the prime \( 2^{255} - 19 \).

Standard base point \( B \) with known prime order \( q \approx 2^{252} : (9, \sqrt{39420360} \mod 2^{255} - 19) \).

Also choose a high-speed, high-security hash function \( H \).
I offer US$1000 prize for the public Rumba20 cryptanalysis that I consider most interesting. Awarded at the end of 2007.

Rumba20 is a function from 192 bytes to 64 bytes; designed for collision-resistance.

http://cr.yp.to/rumba20.html
A sensible ElGamal-type system (van Duin, sci.crypt, 2006):

Signer has 32-byte secret key $k$.

Everyone knows sender’s 32-byte public key: compressed $kB$.

Here $kB = k$th multiple of $B$ in the Curve25519 group.

To verify $(m, \text{compressed } R, t)$:
verify $tB = H(R, m)R + kB$.

To sign $m$: generate a secret $s$;
$R = sB; \ t = H(R, m)s + k \mod q$.

No tricky inversions mod $q$.
More advantages, as we’ll see.
Elliptic-curve arithmetic

Consider all pairs of real numbers $x, y$ such that $y^2 - 5xy = x^3 - 7$.

The “points on the elliptic curve $y^2 - 5xy = x^3 - 7$ over $\mathbb{R}$” are those pairs and one additional point, $\infty$.

i.e. The set of points is

$\{(x, y) \in \mathbb{R}^2 : y^2 - 5xy = x^3 - 7\} \cup \{\infty\}$.

($\mathbb{R}$ is the set of real numbers.)
Graph of this set of points:

Don’t forget ∞.
Visualize ∞ as top of y axis.
Elliptic-curve addition law:
Similar example, an elliptic curve over a finite field:

Consider the prime field \( \mathbb{Z}/13 = \{0, 1, 2, 3, 4, 5, \ldots, 12\} \) with \(-, +, \cdot, /\) defined mod 13.

The “set of points on the elliptic curve \( y^2 - 5xy = x^3 - 7 \) over \( \mathbb{Z}/13 \)” is

\[
\{(x, y) \in (\mathbb{Z}/13)^2 : y^2 - 5xy = x^3 - 7\} \cup \{\infty\}.
\]
Graph of this set of points:

As before, don’t forget $\infty$. 
Example of line over $\mathbb{Z}/13$:

Formula for this line: $y = 7x + 9$. 
Elliptic-curve addition law:

\[ P + Q \]
Complete definition of addition:

\[ x \neq x': (x, y) + (x', y') = (x'', y'') \]

where \( \lambda = (y' - y)/(x' - x) \),
\[ x'' = \lambda^2 - 5\lambda - x - x', \]
\[ y'' = 5x'' - (y + \lambda(x'' - x)). \]

\[ 2y \neq 5x: (x, y) + (x, y) = (x'', y'') \]

where \( \lambda = (5y + 3x^2)/(2y - 5x) \),
\[ x'' = \lambda^2 - 5\lambda - 2x, \]
\[ y'' = 5x'' - (y + \lambda(x'' - x)). \]

\[ (x, y) + (x, 5x - y) = \infty. \]

\[ (x, y) + \infty = (x, y). \]

\[ \infty + (x, y) = (x, y). \]

\[ \infty + \infty = \infty. \]
Addition-law annoyances

1. First \((x, y) + (x', y')\) formula fails if \((x, y) = (x', y')\).
   Must check, use second formula.
   Can attacker see different timing?
   Extra implementation work to avoid side-channel leaks.

2. More exceptional cases.
   Can attacker trigger these?
   Does implementation always follow the published protocol?

3. Tons of field arithmetic.
   Is this fast enough?
Normally use fractions $X/Z, Y/Z$ (or $X/Z^2, Y/Z^3$: “Jacobian”) to avoid divisions, saving time.

But need many multiplications. Can some be eliminated?

Some other elliptic-curve shapes (“Jacobi intersection,” “Jacobi quartic,” “Hessian”) try to unify doublings with generic additions.

Still have exceptional cases. Can exceptions be eliminated?
Interlude: Torus-based crypto

The circle
\[ \{ (x, y) \in \left( \mathbb{Z} / (2^{255} - 949) \right)^2 : x^2 + y^2 = 1 \} \]
has a standard addition law:
\[ (x_1, y_1) + (x_2, y_2) = (x_3, y_3) \]
where
\[ x_3 = x_1 y_2 + y_1 x_2 \]
and
\[ y_3 = y_1 y_2 - x_1 x_2. \]

Not many multiplications.
No exceptional cases.

But also not elliptic.
Broken by number-field sieve unless field is replaced by a much larger field.
News: Edwards curves

e.g. \( x^2 + y^2 = 1 - 30x^2y^2 \):
Choose a field $K$ with $2 \neq 0$ and a parameter $d \in K - \{0,1\}$.

Edwards addition law for
\[
\{(x, y) \in K^2 : \quad x^2 + y^2 = 1 + dx^2y^2\}
\]

is
\[
x_3 = \frac{x_1y_2 + y_1x_2}{1 + dx_1x_2y_1y_2},
\]
\[
y_3 = \frac{y_1y_2 - x_1x_2}{1 - dx_1x_2y_1y_2}.
\]

The Edwards addition law corresponds to the standard addition law on an elliptic curve.
If \( d \) is not a square then the Edwards addition law is complete:
no exceptional cases; the denominators are never 0.

If \( x_1^2 + y_1^2 = 1 + dx_1^2 y_1^2 \)
and \( x_2^2 + y_2^2 = 1 + dx_2^2 y_2^2 \)
then \( dx_1 x_2 y_1 y_2 \) can’t be \( \pm 1 \).

Outline of proof:
If \( (dx_1 x_2 y_1 y_2)^2 = 1 \) then
\[
(x_1 + dx_1 x_2 y_1 y_2 y_1)^2 =
\]
\[
dx_1^2 y_1^2 (x_2 + y_2)^2.
\]
Conclude that \( d \) is a square.
But \( d \) is not a square! Q.E.D.
In particular,
choose $K = \mathbb{Z}/(2^{255} - 19)$
and $d = 121665/121666$.

$K$ doesn’t have $\sqrt{d}$, 
so the Edwards addition law 
for $x^2 + y^2 = 1 + dx^2y^2$
is complete.

This addition law corresponds to 
the standard addition law 
on Curve25519!

Easy map: $x = \sqrt{486664u}/v$, $y = (u - 1)/(u + 1)$.

Can use the Edwards addition law 
for Curve25519 computations.
Computations on Edwards curves

To avoid divisions, use

\((X : Y : Z)\) with \(Z \neq 0\) and

\((X^2 + Y^2)Z^2 = Z^4 + dX^2Y^2\)

to represent \((X/Z, Y/Z)\)
on the Edwards curve

\(x^2 + y^2 = 1 + dx^2y^2.\)

Recall the Edwards addition law:

\[
\begin{align*}
x_3 &= \frac{x_1y_2 + y_1x_2}{1 + dx_1x_2y_1y_2}, \\
y_3 &= \frac{y_1y_2 - x_1x_2}{1 - dx_1x_2y_1y_2}.
\end{align*}
\]
Clear denominators:

\[ X_3 = Z_1 Z_2 (X_1 Y_2 + Y_1 X_2) \]
\[ \cdot (Z_1^2 Z_2^2 - d X_1 X_2 Y_1 Y_2), \]

\[ Y_3 = Z_1 Z_2 (Y_1 Y_2 - X_1 X_2) \]
\[ \cdot (Z_1^2 Z_2^2 + d X_1 X_2 Y_1 Y_2), \]

\[ Z_3 = (Z_1^2 Z_2^2 - d X_1 X_2 Y_1 Y_2) \]
\[ \cdot (Z_1^2 Z_2^2 + d X_1 X_2 Y_1 Y_2). \]

Rewrite \( x_1 y_2 + x_2 y_1 \) as
\[ (x_1 + y_1)(x_2 + y_2) - x_1 x_2 - y_1 y_2, \]
exploit common subexpressions.

12 multiplications (one by \( d \),
one a squaring), 7 additions.
Still complete.
Comparison of addition costs if curve parameters are small:

<table>
<thead>
<tr>
<th>System</th>
<th>Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>Doche/Icart/Kohel</td>
<td>$12M + 5S$</td>
</tr>
<tr>
<td>Jacobian</td>
<td>$11M + 5S$</td>
</tr>
<tr>
<td>Jacobi intersection</td>
<td>$13M + 2S$</td>
</tr>
<tr>
<td>Projective</td>
<td>$12M + 2S$</td>
</tr>
<tr>
<td>Jacobi quartic</td>
<td>$10M + 3S$</td>
</tr>
<tr>
<td>Hessian</td>
<td>$12M$</td>
</tr>
<tr>
<td>Edwards</td>
<td>$10M + 1S$</td>
</tr>
</tbody>
</table>

Can save time in “mixed additions” ($Z_2 = 1$) and in “readditions”; slightly different order of systems.
Can save time in doubling:
rewrite $1 + dx_1^2 y_1^2$ as $x_1^2 + y_1^2$
(as suggested by Marc Joye);
rewrite $1 - dx_1^2 y_1^2$ as $2 - x_1^2 - y_1^2$;
exploit common subexpressions.

\[ B = (X_1 + Y_1)^2, \quad C = X_1^2, \quad D = Y_1^2, \]
\[ E = C + D, \quad H = Z_1^2, \]
\[ J = E - 2H, \quad X_3 = (B - E)J, \]
\[ Y_3 = E(C - D), \quad Z_3 = EJ. \]

7 multiplications
(4 of which are squarings),
6 additions.
Comparison of doubling costs if curve parameters are small:

<table>
<thead>
<tr>
<th>System</th>
<th>Cost</th>
</tr>
</thead>
<tbody>
<tr>
<td>Projective</td>
<td>5M + 6S</td>
</tr>
<tr>
<td>Projective if $a = -3$</td>

</tr>
<tr>
<td>Doche/Icart/Kohel</td>
<td>2M + 5S</td>
</tr>
</tbody>
</table>

Several new algorithms here.

Explicit-Formulas Database:
http://www.hyperelliptic.org/EFD
Consequences for signatures

Edwards coordinates vs. popular $a = -3$ Jacobian coordinates in standard cost model:

$\approx 5\%$ faster for $t \mapsto tB$

using typical $B$ precomputation.

$\approx 15\%$ faster for $h, R \mapsto hR$.

$\approx 13\%$ faster for $t, h, R \mapsto tB - hR$ using “JSF.”

$\approx 38\%$ faster for batch verification via Bos-Coster.

Plus: complete, low memory, . . .
Batch verification of many
\[ t_i B - h_i R_i - S_i = 0: \]
choose random 128-bit \( v_i \),
check \( \left( \sum_i v_i t_i \right) B - \sum_i (v_i h_i) R_i - \sum_i v_i S_i = 0. \)
(Bellare/Garay/Rabin, LATIN '98)

Use subtractive multi-scalar
multiplication algorithm
(credited to Bos and Coster by
de Rooij, EUROCRYPT '94).

Only \( \approx 25.2 \) curve adds/bit
to verify 100 signatures.

Use Edwards coordinates!
