Tanja Lange Technische Universiteit Eindhoven

In this talk $\log L$ means $(1+o(1))(\log N)^{1/3}(\log\log N)^{2/3}$. L is often written $(L_N(1/3))''$ or $(L_N(1/3))^{1+o(1)}''$.

Exponents of L in this talk are limited to $10^{-6}\mathbf{Z}$.

Rigorously proven? Ha ha ha.

2003 Shamir-Tromer, 2003 Lenstra-Tromer-Shamir-Kortsmit-Dodson-Hughes-Leyland, 2005 Geiselmann-Shamir-Steinwandt-Tromer, 2005 Franke-Kleinjung-Paar-Pelzl-Priplata-Stahlke, etc.: RSA-1024 is breakable in a year by an attack machine costing $<10^9$ dollars.

2003 Shamir-Tromer, 2003 Lenstra-Tromer-Shamir-Kortsmit-Dodson-Hughes-Leyland, 2005 Geiselmann-Shamir-Steinwandt-Tromer, 2005 Franke-Kleinjung-Paar-Pelzl-Priplata-Stahlke, etc.: RSA-1024 is breakable in a year by an attack machine costing $<10^9$ dollars.

So the Internet switched to RSA-2048, and we no longer care about RSA-1024 security, right?

2003 Shamir-Tromer, 2003 Lenstra-Tromer-Shamir-Kortsmit-Dodson-Hughes-Leyland, 2005 Geiselmann-Shamir-Steinwandt-Tromer, 2005 Franke-Kleinjung-Paar-Pelzl-Priplata-Stahlke, etc.: RSA-1024 is breakable in a year by an attack machine costing $<10^9$ dollars.

So the Internet switched to RSA-2048, and we no longer care about RSA-1024 security, right?

Wrong!

Example: The IP address of dnssec-deployment.org is signed by an RSA-1024 key

Example: The IP address of dnssec-deployment.org is signed by an RSA-1024 key signed by an RSA-2048 key

Example: The IP address of dnssec-deployment.org is signed by an RSA-1024 key signed by an RSA-2048 key signed by org's RSA-1024 key

Example: The IP address of dnssec-deployment.org is signed by an RSA-1024 key signed by an RSA-2048 key signed by org's RSA-1024 key signed by an RSA-2048 key

Example: The IP address of dnssec-deployment.org is signed by an RSA-1024 key signed by an RSA-2048 key signed by org's RSA-1024 key signed by an RSA-2048 key signed by a root RSA-1024 key

Example: The IP address of dnssec-deployment.org is signed by an RSA-1024 key signed by an RSA-2048 key signed by org's RSA-1024 key signed by an RSA-2048 key signed by a root RSA-1024 key signed by an RSA-2048 key.

Example: The IP address of dnssec-deployment.org is signed by an RSA-1024 key signed by an RSA-2048 key signed by org's RSA-1024 key signed by an RSA-2048 key signed by a root RSA-1024 key signed by an RSA-2048 key.

Most "DNSSEC" signatures follow a similar pattern.

Example: The IP address of dnssec-deployment.org is signed by an RSA-1024 key signed by an RSA-2048 key signed by org's RSA-1024 key signed by an RSA-2048 key signed by a root RSA-1024 key signed by an RSA-2048 key.

Most "DNSSEC" signatures follow a similar pattern.

Another example: SSL has used many millions of RSA-1024 keys. Imagine that an attacker has recorded tons of SSL traffic.

Users seem unconcerned:

- 1. "The attack machine costs more than this RSA key is worth."
- 2. "The attack machine isn't off-the-shelf; it's only for attackers building ASICs."
- 3. For signatures: "We switch keys every month, and the attack machine takes a year."

Users seem unconcerned:

- 1. "The attack machine costs more than this RSA key is worth."
- 2. "The attack machine isn't off-the-shelf; it's only for attackers building ASICs."
- 3. For signatures: "We switch keys every month, and the attack machine takes a year."

Real quote: "DNSSEC signing keys should be large enough to avoid all known cryptographic attacks during the effectivity period of the key."

Continuation of quote: "To date, despite huge efforts, no one has broken a regular 1024-bit key; in fact, the best completed attack is estimated to be the equivalent of a 700-bit key. An attacker breaking a 1024-bit signing key would need to expend phenomenal amounts of networked computing power in a way that would not be detected in order to break a single key. Because of this, it is estimated that most zones can safely use 1024-bit keys for at least the next ten years."

Goal of our "Batch NFS" paper: analyze the asymptotic cost, specifically price-performance ratio, of breaking many RSA keys.

"Many": e.g. millions.

"Price-performance ratio": area-time product for chips.

"RAM" metric (adding two 64-bit integers has same cost as accessing array of size 2^{64}) is not realistic; "AT" metric is realistic.

"Asymptotic": We systematically suppress polynomial factors. Our speedups are superpolynomial.

Best result known for *one* key: time $L^{1.185632}$ using chip area $L^{0.790420}$; AT is $L^{1.976052}$.

Best result known for *one* key: time $L^{1.185632}$ using chip area $L^{0.790420}$; AT is $L^{1.976052}$.

Our main result for a batch of $L^{0.5}$ keys: time $L^{1.022400}$ using chip area $L^{1.181600}$; AT per key is $L^{1.704000}$.

Best result known for *one* key: time $L^{1.185632}$ using chip area $L^{0.790420}$; AT is $L^{1.976052}$.

Our main result for a batch of $L^{0.5}$ keys: time $L^{1.022400}$ using chip area $L^{1.181600}$; AT per key is $L^{1.704000}$.

This paper also looks more closely at $L^{o(1)}$, analyzing asymptotic speedup from early-abort ECM. Results are not what one would guess from 1982 Pomerance.

Asymptotic consequences:

- Attack cost per key
 is reduced, so attacker
 can target lower-value keys.
- 2. Primary bottleneck is low-memory factorization—well suited for off-the-shelf graphics cards.
- 3. Attack time is reduced (and can be reduced more), breaking key rotation.

Asymptotic consequences:

- 1. Attack cost per key is reduced, so attacker can target lower-value keys.
- 2. Primary bottleneck is low-memory factorization—well suited for off-the-shelf graphics cards.
- 3. Attack time is reduced (and can be reduced more), breaking key rotation.

"Do the asymptotics really kick in before 1024 bits?" — Maybe not, but no basis for confidence.

Eratosthenes for smoothness

Sieving small integers i > 0 using primes 2, 3, 5, 7:

1 2 3 4 5 6 7 8 9 0 11 12 3 14 15 16 17 18 19	2	2	
4	22	3	E
6	2	3	5

9		33	
10	2		5
11			
12	22	3	
13			_
14	2	2	_ 7
15		3	5
10 17	2222	2	
10	2	2.2	
Ιδ 10	2	33	
19 20	22		_
ZU	22		<u> </u>

612	2	2			3	3						
613												
614	2											
615					3			5				
616	2	2	2									7
617												
618	2				3							
619												
620	2	2						5				
621					3	3	3					
622	2											
623												7
624	2	2	2	2	3							
625								5	5	5	5	
626	2											
627					3							
628	2	2										
629												
630	2				3	3		5				7
631												

etc.

Have complete factorization of the congruences $i \equiv 611 + i$ for some i's.

$$14 \cdot 625 = 2^1 3^0 5^4 7^1$$

$$64 \cdot 675 = 2^6 3^3 5^2 7^0$$

$$75 \cdot 686 = 2^1 3^1 5^2 7^3$$
.

$$=2^83^45^87^4=(2^43^25^47^2)^2.$$

$$\gcd\{611, 14 \cdot 64 \cdot 75 - 2^4 3^2 5^4 7^2\}$$

= 47.

$$611 = 47 \cdot 13$$
.

The number-field sieve

Generalize $i \equiv i + N \pmod{N}$ $\rightarrow a \equiv a + bN \pmod{N}$ $\rightarrow a - bm \equiv a - b\alpha \pmod{m - \alpha}$ for root $\alpha \in \mathbf{C}$ of nonzero integer poly.

For any m can find α so that factoring $m-\alpha$ produces factorization of N.

Optimal choice of $\log m$ is $(\mu + o(1))(\log N)^{2/3}(\log \log N)^{1/3}$.

1993 Buhler–Lenstra–Pomerance: Smoothness bound $L^{0.961500}$. Sieve $L^{1.923000}$ pairs (a, b). Find $L^{0.961500}$ pairs with a-bm and $a-b\alpha$ smooth. Total RAM time $L^{1.923000}$.

1993 Coppersmith: Total RAM time $L^{1.901884}$ using multiple number fields.

(Multiple number fields don't seem to combine well with AT, factory, et al.)

Sieving is a disaster in realistic cost metric. $AT \cos L^{2.403750}$.

Sieving is a disaster in realistic cost metric. $AT \cos L^{2.403750}$.

Fix: find smooth using ECM. AT cost $L^{1.923000}$.

Sieving is a disaster in realistic cost metric. $AT \cos L^{2.403750}$.

Fix: find smooth using ECM. $AT \cos L^{1.923000}$.

Linear algebra is also a disaster. $AT \cos L^{2.403750}$.

Sieving is a disaster in realistic cost metric. $AT \cos L^{2.403750}$.

Fix: find smooth using ECM. $AT \cos L^{1.923000}$.

Linear algebra is also a disaster. $AT \cos L^{2.403750}$.

Semi-fix: Reduce smoothness bounds to rebalance.

AT cost $L^{1.976052}$.

(2001 Bernstein)

The factorization factory

1993 Coppersmith:

There exists an algorithm that factors any integer with same # bits as N in RAM time $L^{1.638587}$.

Smoothness bound $L^{0.819290}$. Smaller than before, so need more (a, b).

Algorithm knows all (a, b) such that a - bm is smooth. Note: one m works for all N. Algorithm uses ECM to check whether $a - b\alpha_N$ is smooth. Finding this algorithm is slower than running it. Need to precompute all (a, b) such that a - bm is smooth. RAM time $L^{2.006853}$.

Finding this algorithm is slower than running it. Need to precompute all (a, b) such that a - bm is smooth. RAM time $L^{2.006853}$.

Standard conversion of precomputation into batching: if there are enough targets, more than $L^{0.368266}$, then precomputation cost becomes negligible.

Finding this algorithm is slower than running it. Need to precompute all (a, b) such that a - bm is smooth. RAM time $L^{2.006853}$.

Standard conversion of precomputation into batching: if there are enough targets, more than $L^{0.368266}$, then precomputation cost becomes negligible.

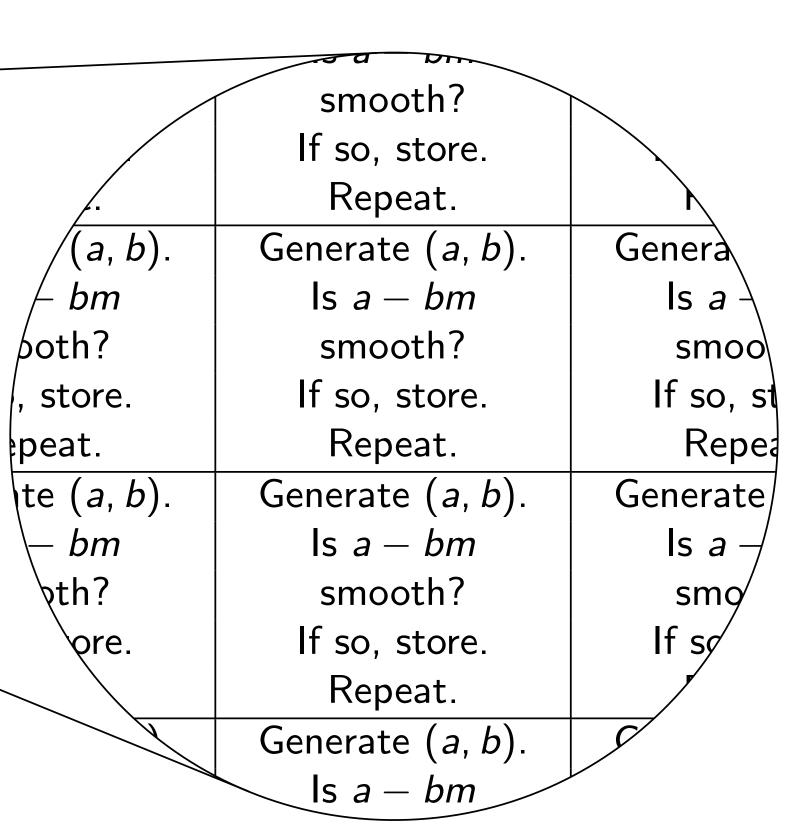

The big problem: Coppersmith's algorithm has size $L^{1.638587}$. Huge AT cost; useless in reality.

Batch NFS

Goal: Optimize AT asymptotics.

- 1. Generate (a, b) in parallel. Test a - bm for smoothness.
- 2. Make many copies of each N, close to each (a, b) generator. When smooth a bm is found, test each $a b\alpha_N$ for smoothness.
- 3. After all smooths are found, reorganize: for each N, bring relevant (a, b) close together.
- 4. Linear algebra.
